

README

This repo was created for sharing my solution to the assignment from Nearfield Instruments.

The assignment is explained in: [Assignments_QA_Engineer.docx](#), and the attached two examples file. It consists of two parts, that are mirrored in this repository:

- [Create a system test plan](#)
- [Create a test automation script for robot arm movement verification](#)

These files contain the solution for the two parts respectively.

Initial consideration before going into the details

- System test plan
 - First thought is in Jira & Xray, but that's near impossible to share. Therefore it'll need to be constructed directly in md/csv files, something that is 'ready to import'.
 - Markdown files for descriptions --> Obsidian for a more WYSWYG experience.
 - Csv files for import-ready stuff.
- Test automation script
 - Javascript is a no-no for me
 - Python probably due to token density
 - A very nice follow-up question would be to migrate all to robot framework after stakeholder alignment
 - C# -> I'd love the type-safety & linter. That'll have to be sacrificed. Not a 1:1 replacement, but python type annotations are a good stop-gap measure, especially for enabling the linter to be better
 - VsCode, because that's already installed.
 - Dependency mgmt: On my wsl it seems that I still have a docker installed -> this gets a container ideally. At least a requirements.txt
- Strategy: "The old Esettan style, with George's spin active": clear the core deliverables, plus add support and scaffolding until it resembles a self-contained project/business capability (so no matrix-org reliance. Adapting to that here:
 - The only prereq here is clockify
 - Core functionality: Obsidian & python
 - Docker container
